

Risk Of Liver Failure With Common Drugs

A key ingredient in many drugs that is used widely for relief of pain, fever, headaches is called Acetaminophen or Paracetamol, (APAP).

The number one cause of acute liver failure in the Western world is acetaminophen toxicity. This drug is also the leading cause of overdose in the United States, United Kingdom, Australia and New Zealand. Overdoses can cause liver failure which leads to death. The chances of overdose are increased when used with alcohol or other liver stressors. Unlike painkillers such as aspirin and ibuprofen, this drug is not an anti-inflammatory drug.

Keep in mind, pain is a sign that the body is having a problem. The goal should be solving the problem safely. Call our office for a **free consultation**. We can help!

Yours for health naturally,

Dr B
